

Employee Management System

Constructor Overloading – UML Diagram and Algorithm

1. UML Class Diagram

Employee	
Attributes	Methods
- name : String - id : int - designation : String - salary : double - promotionStatus : String	+ Employee() + Employee(name : String, id : int) + Employee(name : String, id : int, designation : String, salary : do + Employee(name : String, id : int, designation : String, salary : do + display() : void

2. Algorithm

Step 1: Start.

Step 2: Define the Employee class with attributes: name, id, designation, salary and promotionStatus.

Step 3: Define a default constructor to initialize employee details with default values.

Step 4: Define a constructor with name and id parameters.

Step 5: Define a constructor with name, id, designation and salary parameters.

Step 6: Define a constructor with all five parameters.

Step 7: Define the display() method to print employee details.

Step 8: In the main() method, create employee objects using the different overloaded constructors.

Step 9: Call display() for each object to show the employee details.

Step 10: Stop.

Key Concept: Constructor overloading means defining multiple constructors in the same class with different parameter lists.
